

Workflow Detail: Quality Assurance of Data (Pinned Things)

Module 5: Quality Assurance of Data

Task ID	Task Name	Explanations and Comments	Resources
T1	Expert or manager reviews and approves keyed data.	Since resources are seldom available for a manager to review all entered records, an informal or formal sampling scheme is usually required. Sampling schemes are often in the form of: initially review 100 percent of records by a new data capture technician, then reduce to review to 50%. If quality remains high, reduce sampling frequency to as low as about 10%. If problems are found for a given technician, increase sampling frequency as necessary.	
T2	Use automated scripts to check against authority files for existence of misspellings of taxon, geographical, or collector names, and for orthographic and data type inconsistencies.		
T3	Resolve problems identified in T2.	This may involve merging duplicated collecting events or localities, correcting or	

		deleting incorrect data, etc.	
T4	Confirm that records have been checked, when they were checked, and with what results.		
T5	Compare data with that of likely duplicates of the same occurrence or collecting event.		
T6	Cluster data and look for outliers.		
T7	Compare data with related data.	For example, compare taxon name and georeference with known or predicted geographic distribution or dates of collection.	
T8	Expose data to community for expert feedback.		e.g., through Email, FilteredPush (http://wiki.filteredpush.org), institutional website, etc.
