The number of species in any place on earth varies widely by latitude

Number of vertebrate species

The latitudinal diversity gradient is pervasive across taxa:

birds
mammals
reptiles
amphibians
insects
plants

Explanations for the latitudinal diversity gradient generally invoke:

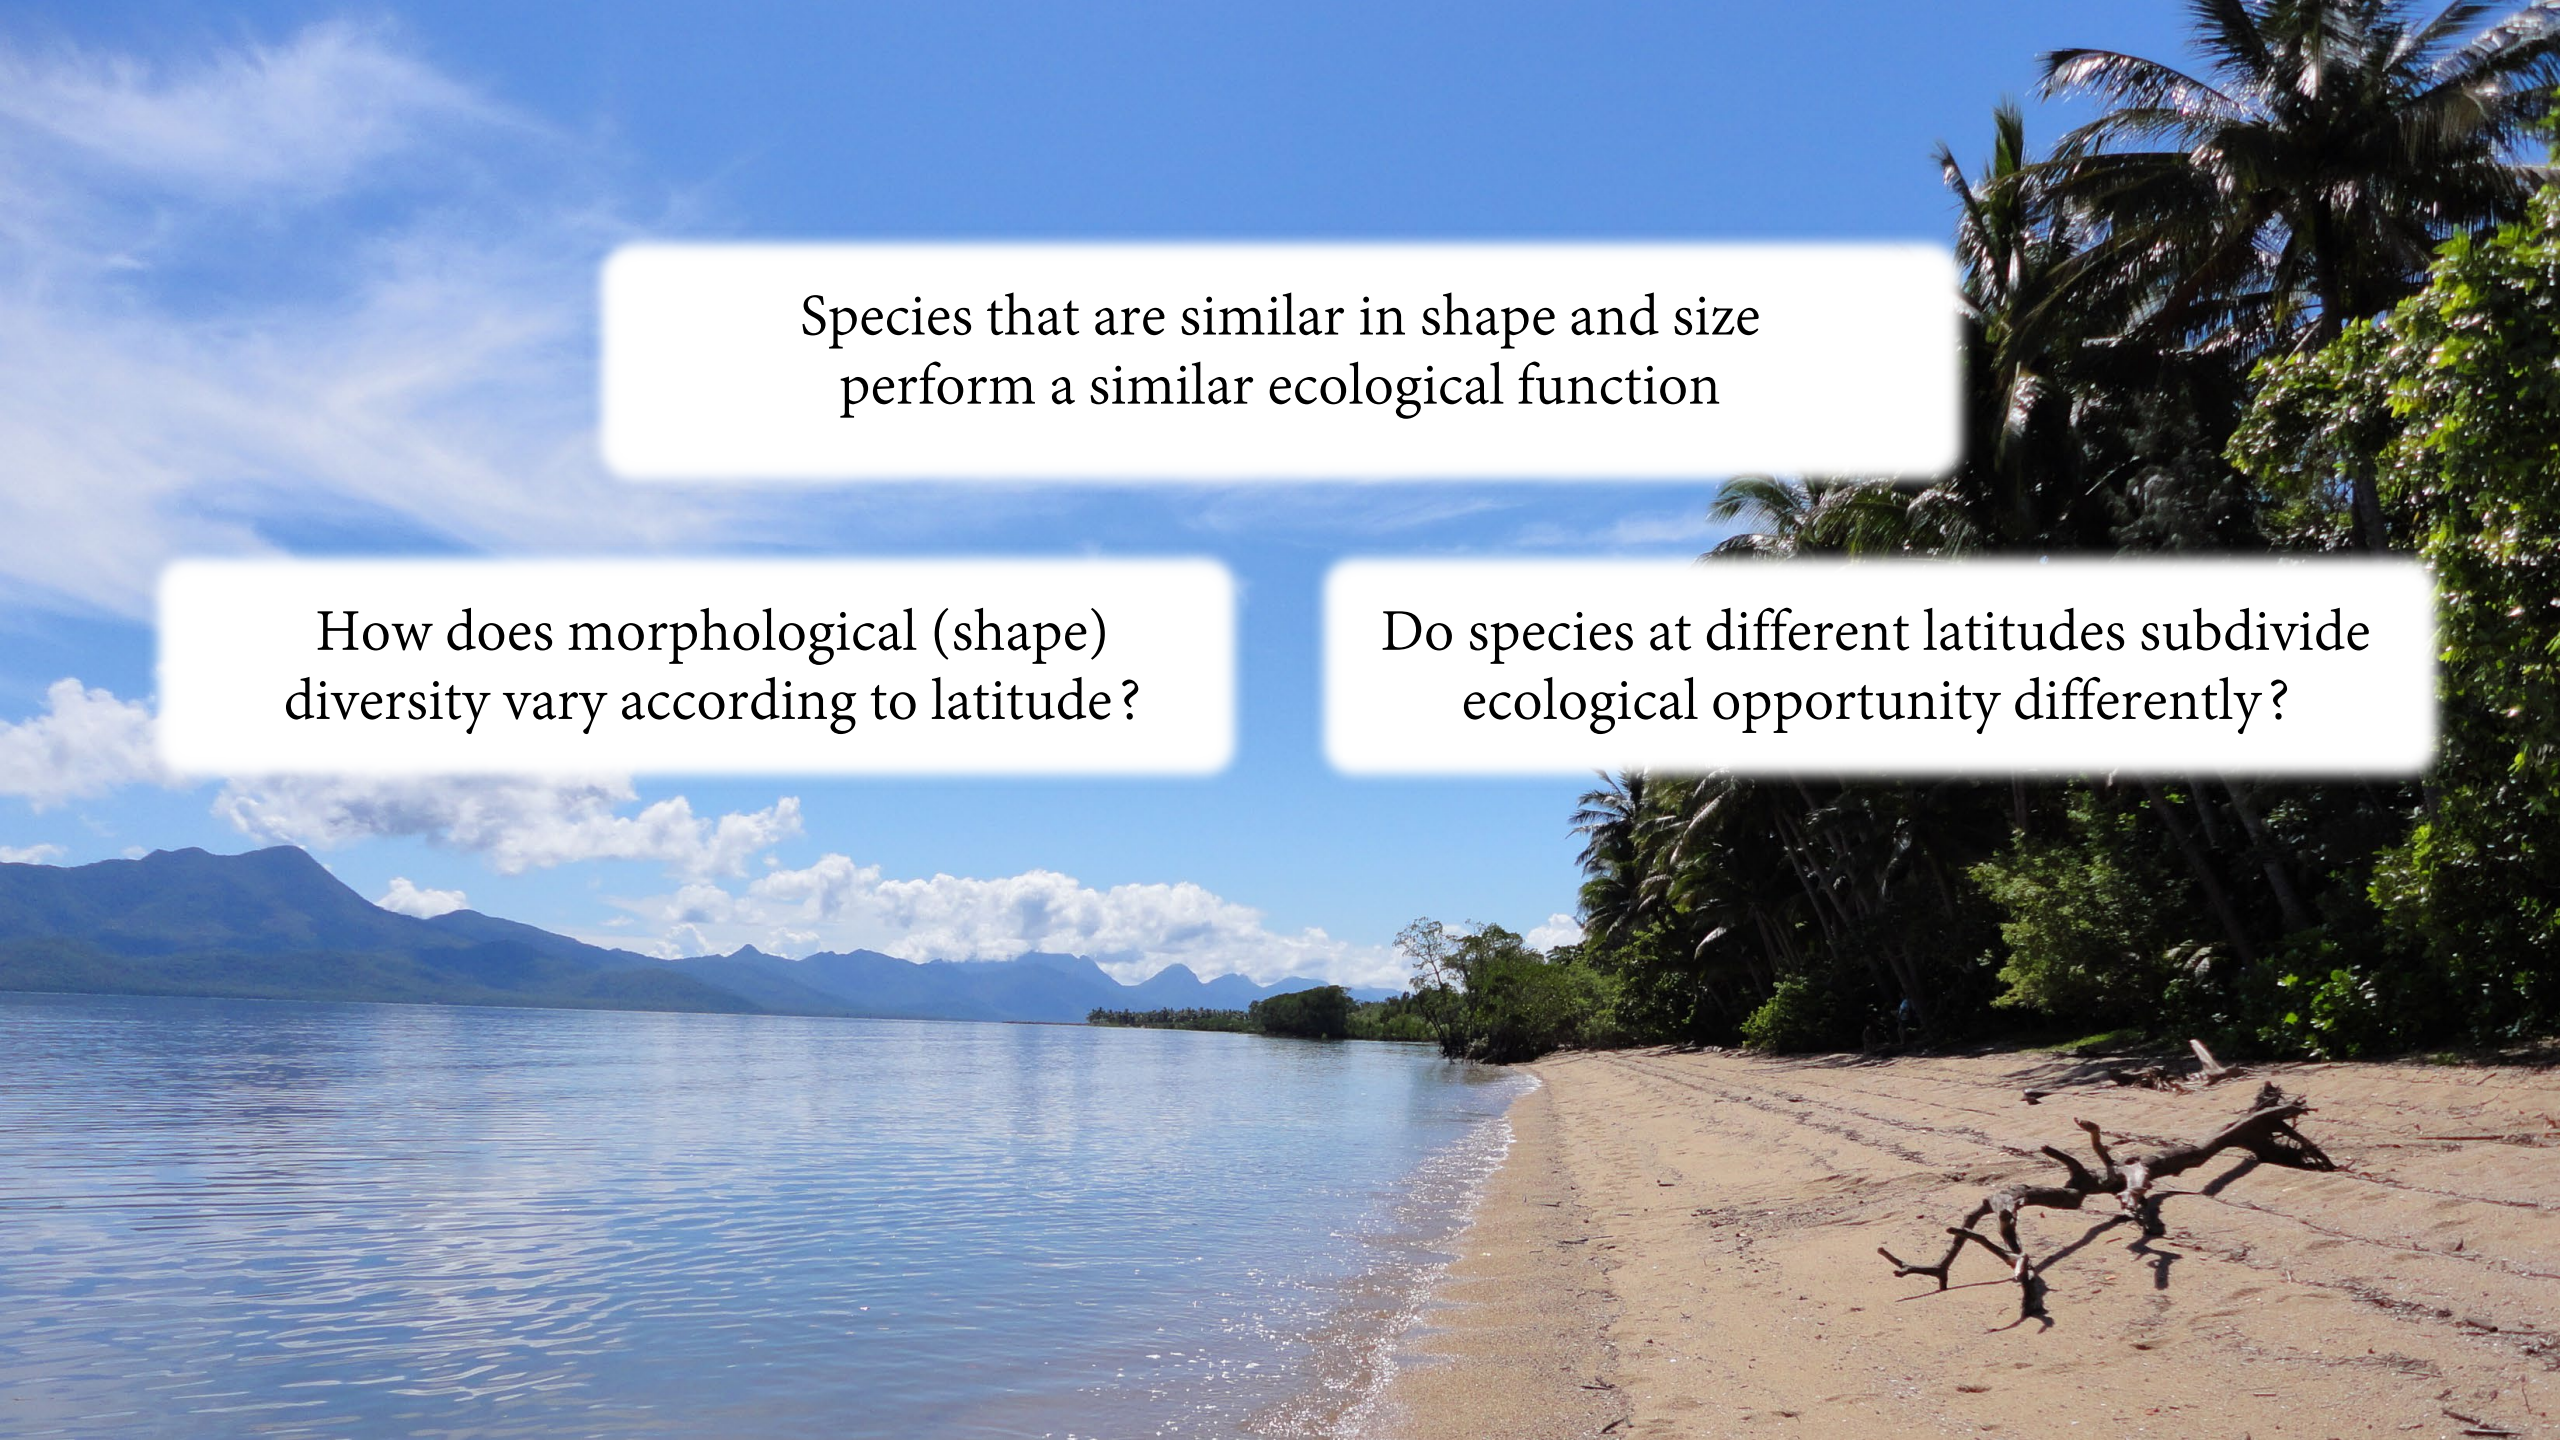

- 1) Differences in diversification rate
- 2) Differences in age and area
- 3) Differences in ecological limits (accommodation)

Species that are similar in shape and size perform a similar ecological function

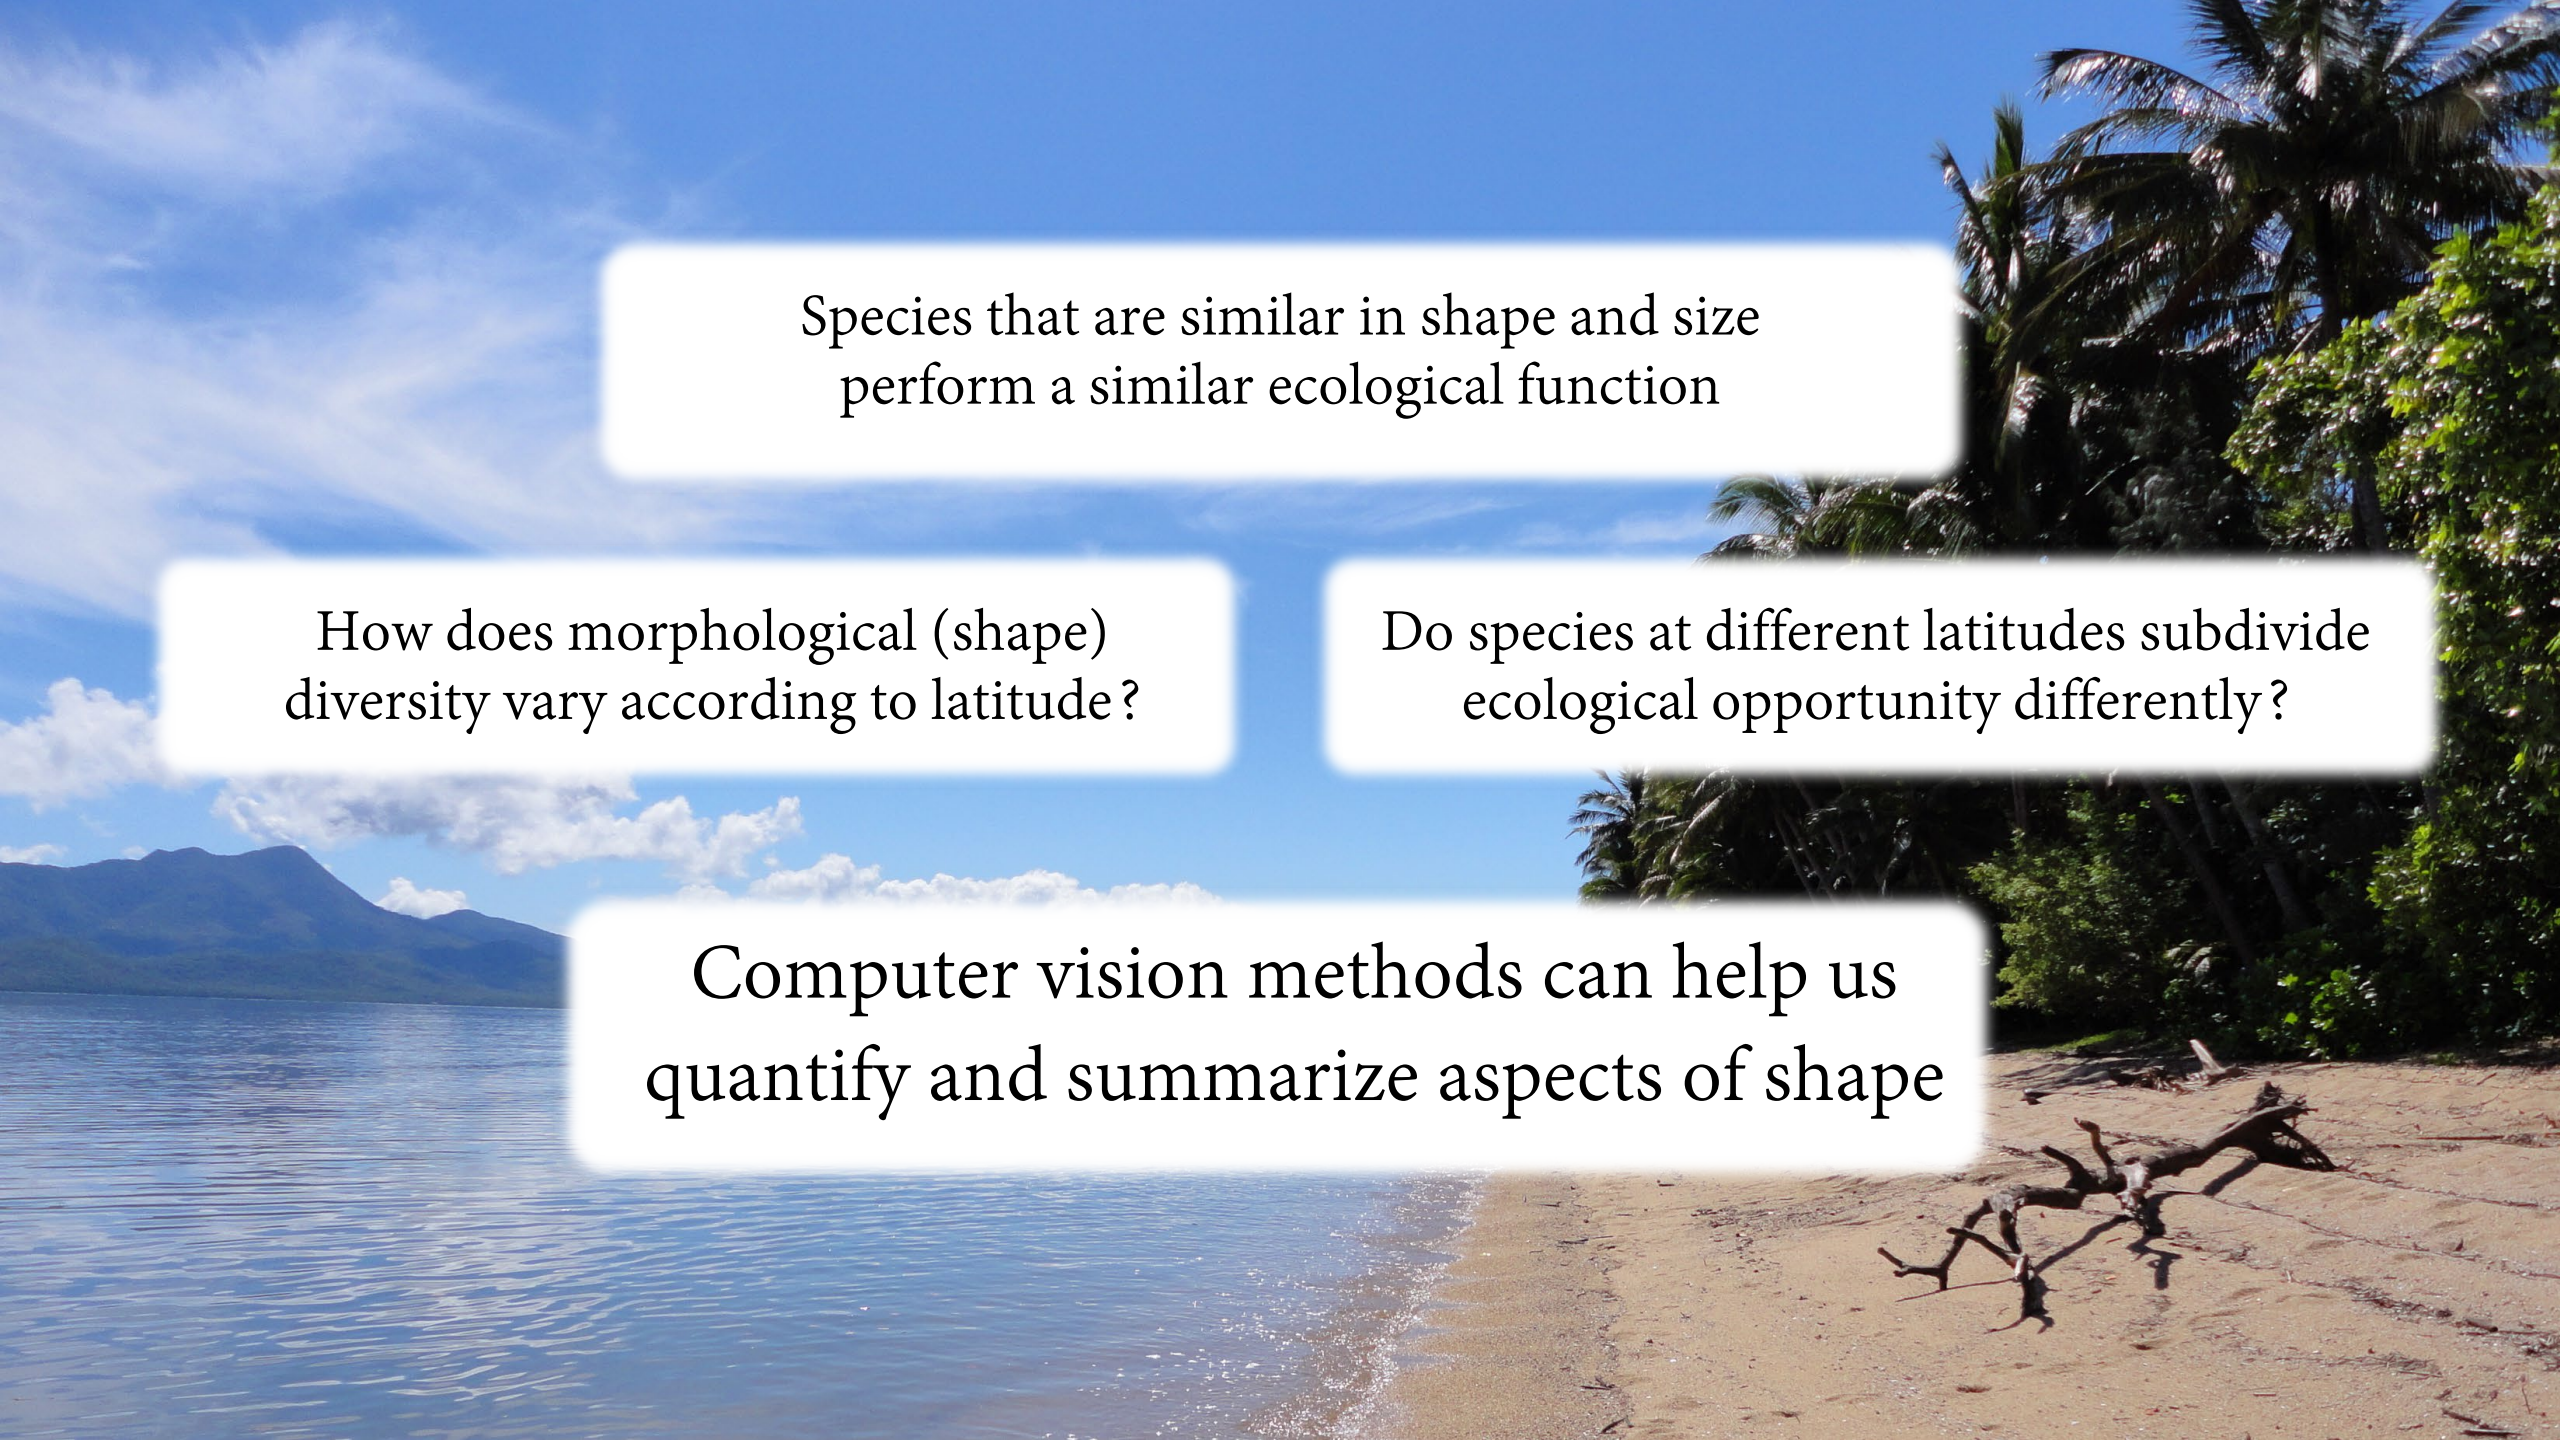

6 different species (*Zosterops*)

A tropical beach scene with a blue sky, palm trees, and a body of water. The sky is bright blue with scattered white clouds. In the foreground, there is a sandy beach with some driftwood. The water is calm and blue. In the background, there are green mountains under a clear sky.

Species that are similar in shape and size
perform a similar ecological function

How does morphological (shape)
diversity vary according to latitude?

Do species at different latitudes subdivide
ecological opportunity differently?

perform a similar ecological function

How does morphological (shape)
diversity vary according to latitude?

Do species at different latitudes subdivide
ecological opportunity differently?

Computer vision methods can help us
quantify and summarize aspects of shape

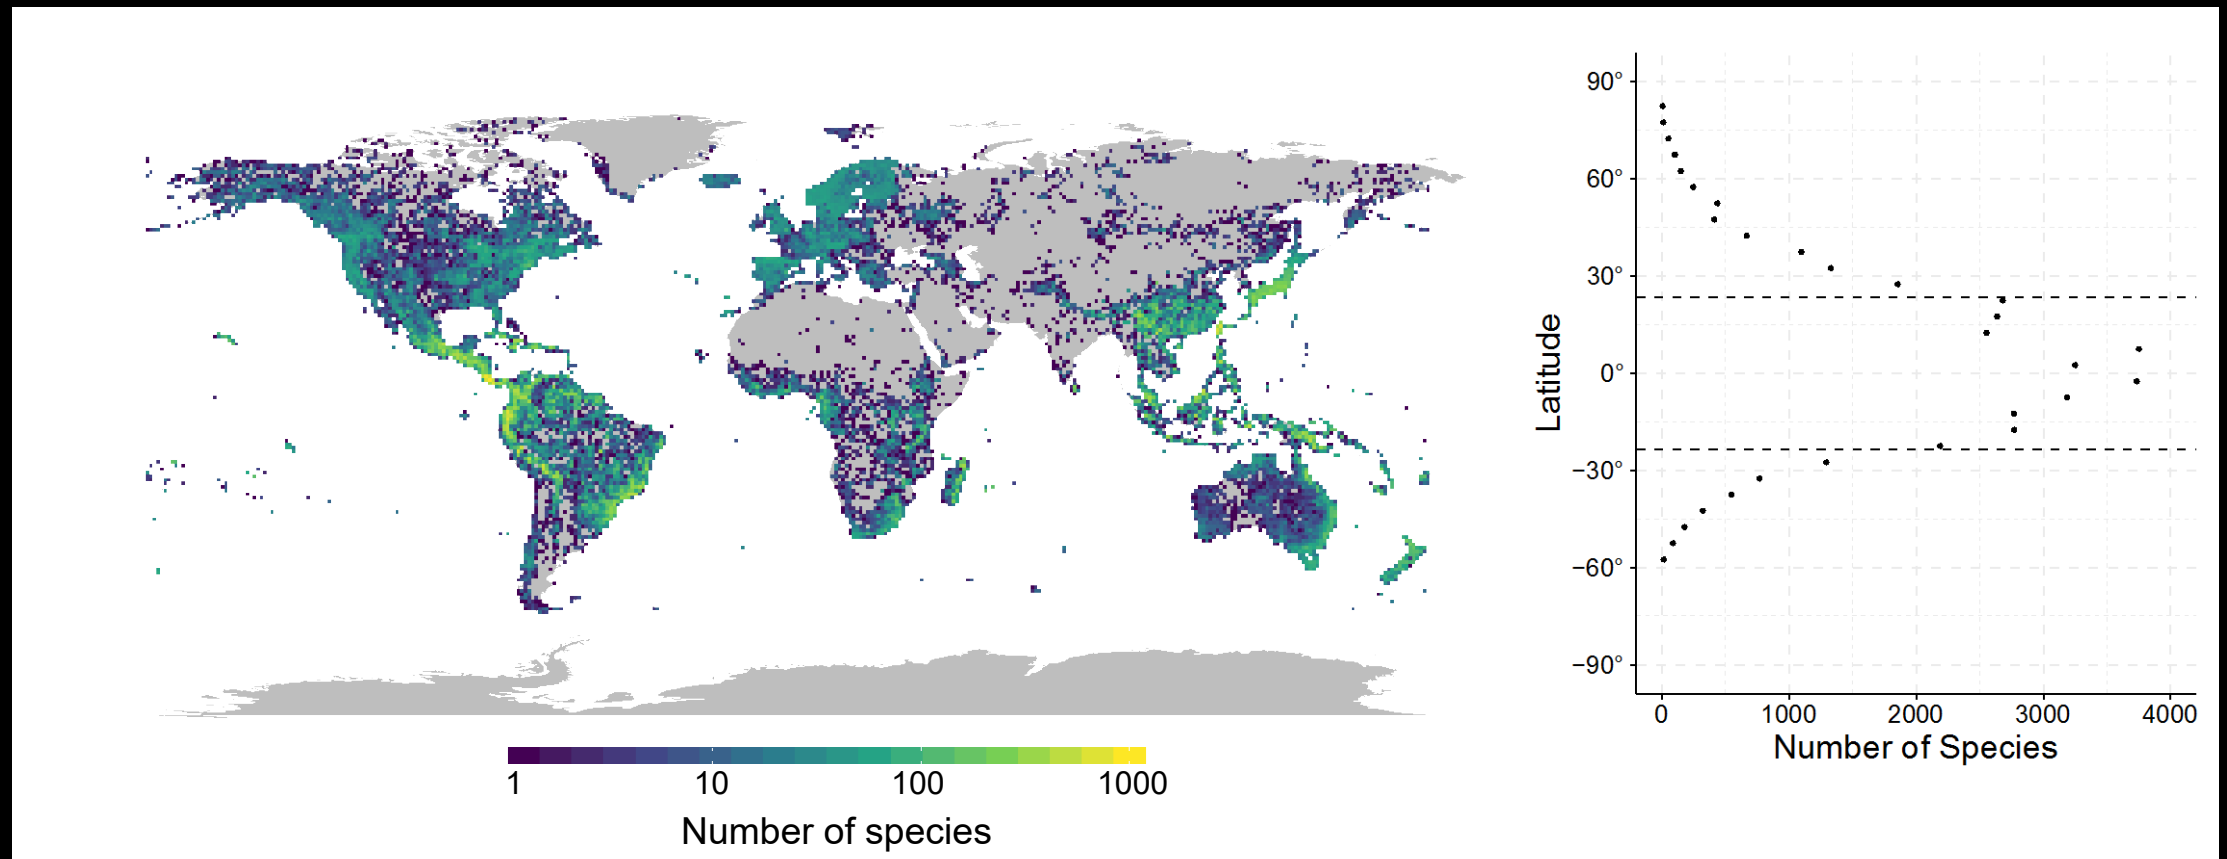

We focus our study on ferns

~12,000 species
distributed globally

Fern species numbers vary according to latitude

Estimated from 1.4 million museum records (GBIF)

Ferns are highly diverse in both size and shape

Ferns are well represented in digitized collections, including the US National Herbarium

Our data:

All available IDigBio specimens for
ferns and lycophytes

~517,000 images

~8600 species

70% global diversity

~320 genera

95% generic diversity

Our computer vision based approach:

80% of data used for training neural network
20% of data set aside for validation

Build a convolutional neural net and train it to label fern specimens:

by genus

>500 specimens (86 genera)

>50 specimens (269 genera)

by species

>50 specimens (1425 species)

We validate the model by feeding images with known labels through the network

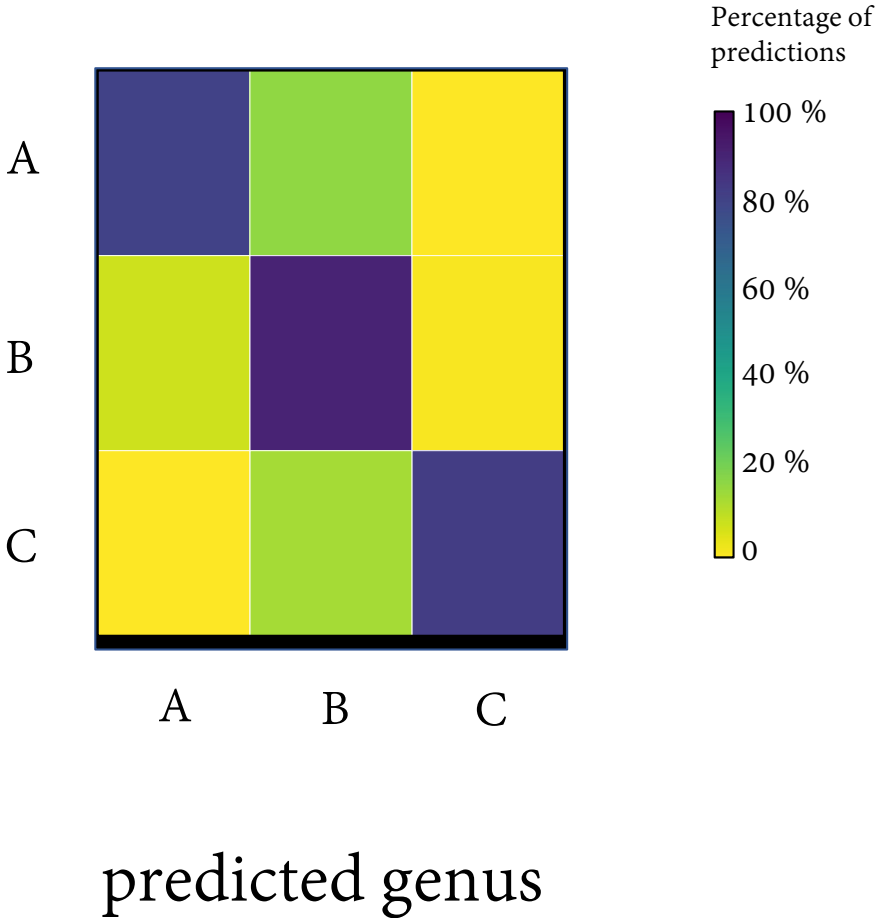

example genus A

example genus B

example genus C

actual genus

FernNet is 97% accurate at genus ID

3 genera in the tree fern family Cyatheaceae

Confusion is most often between closely related genera

Boxes contain examples of genera within the same family

actual genus

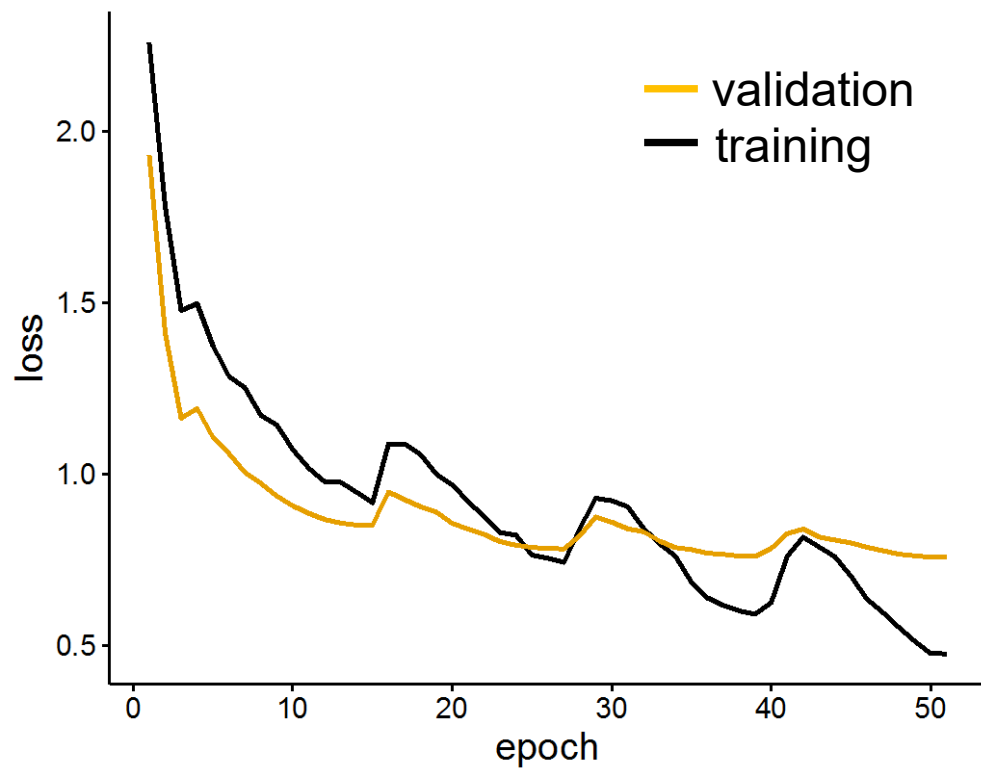

Percentage of predictions

predicted genus

FernNet is highly accurate for species ID (1425 species)

What pixels is FernNet using to make these identifications?

We use the penultimate network layer to quantify shape space occupation

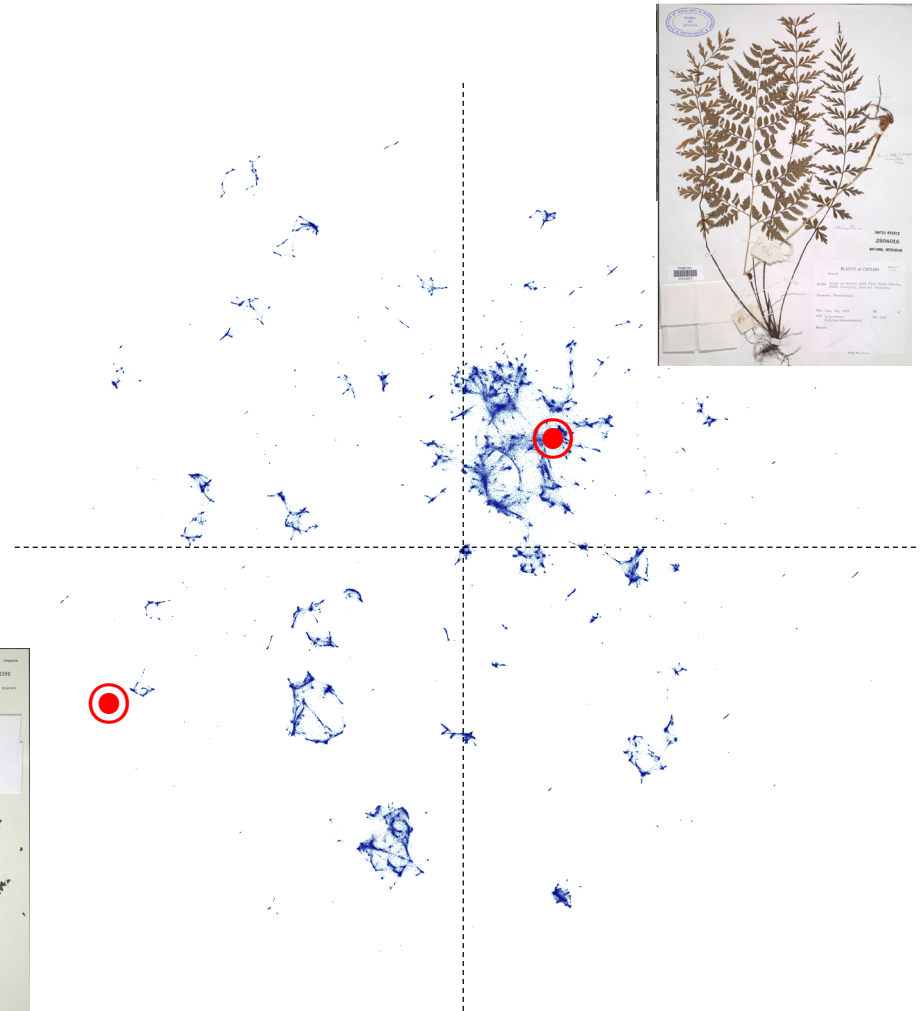

We use the penultimate network layer to quantify shape space occupation

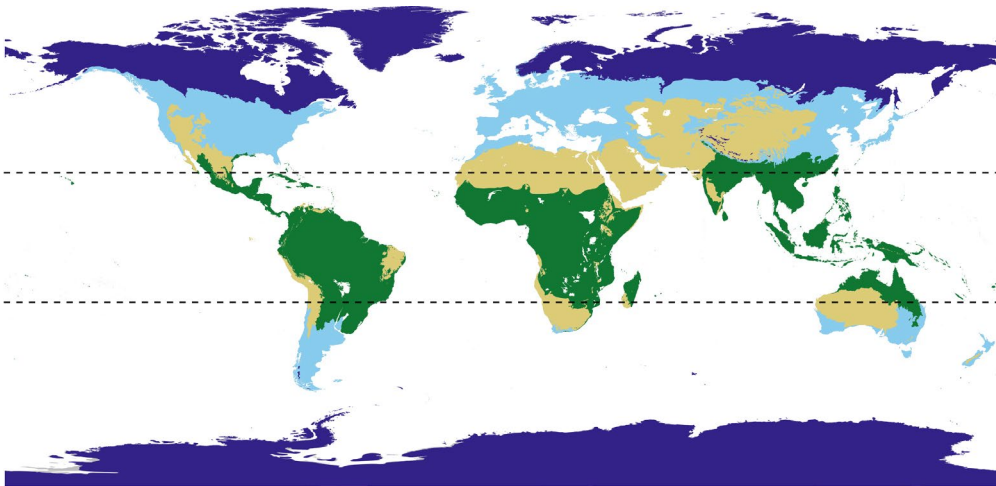

Ferns specimens generate a complex morphological landscape

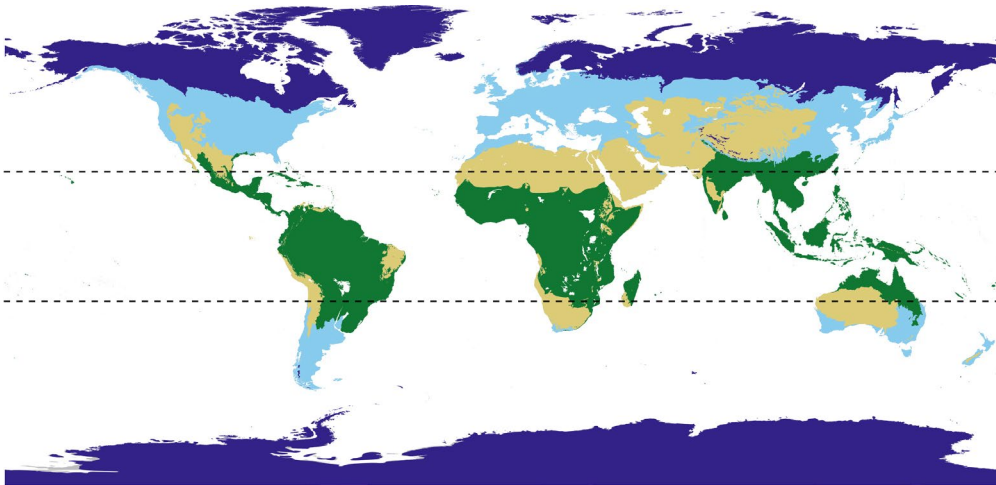

Ferns specimens generate a complex morphological landscape

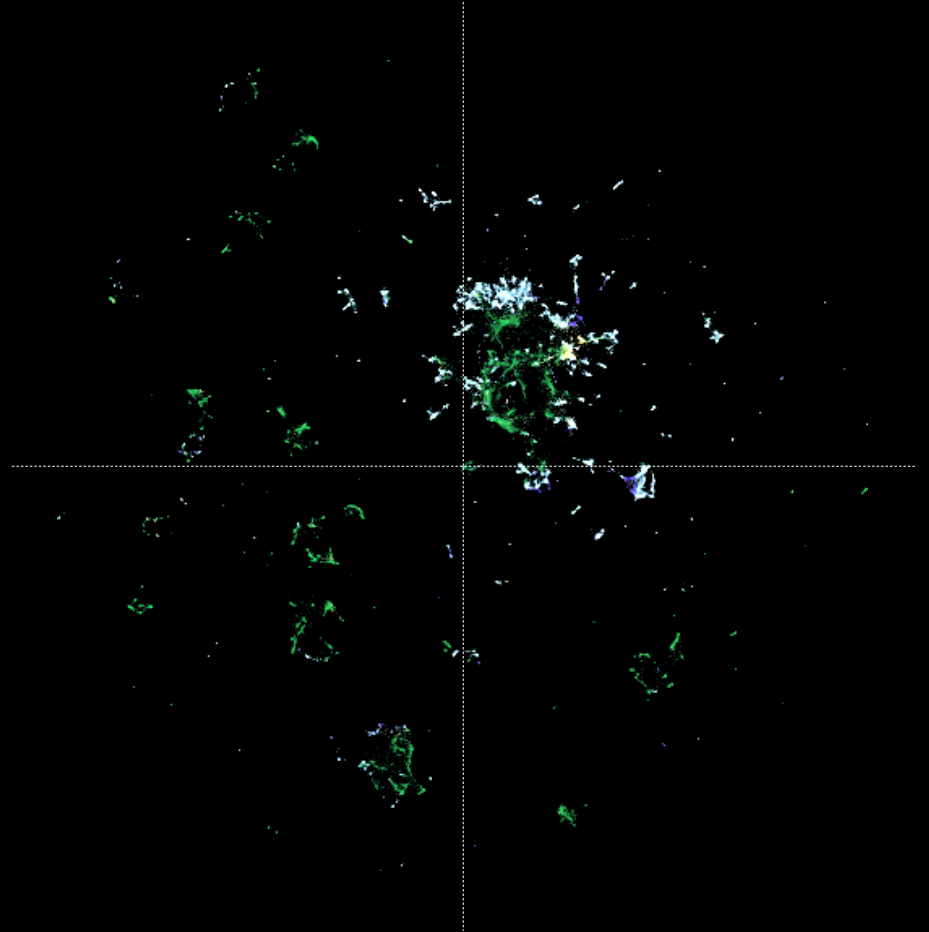

Ferns specimens generate a complex morphological landscape

Ferns specimens generate a complex morphological landscape

...with clusters of variation based on latitude and climate

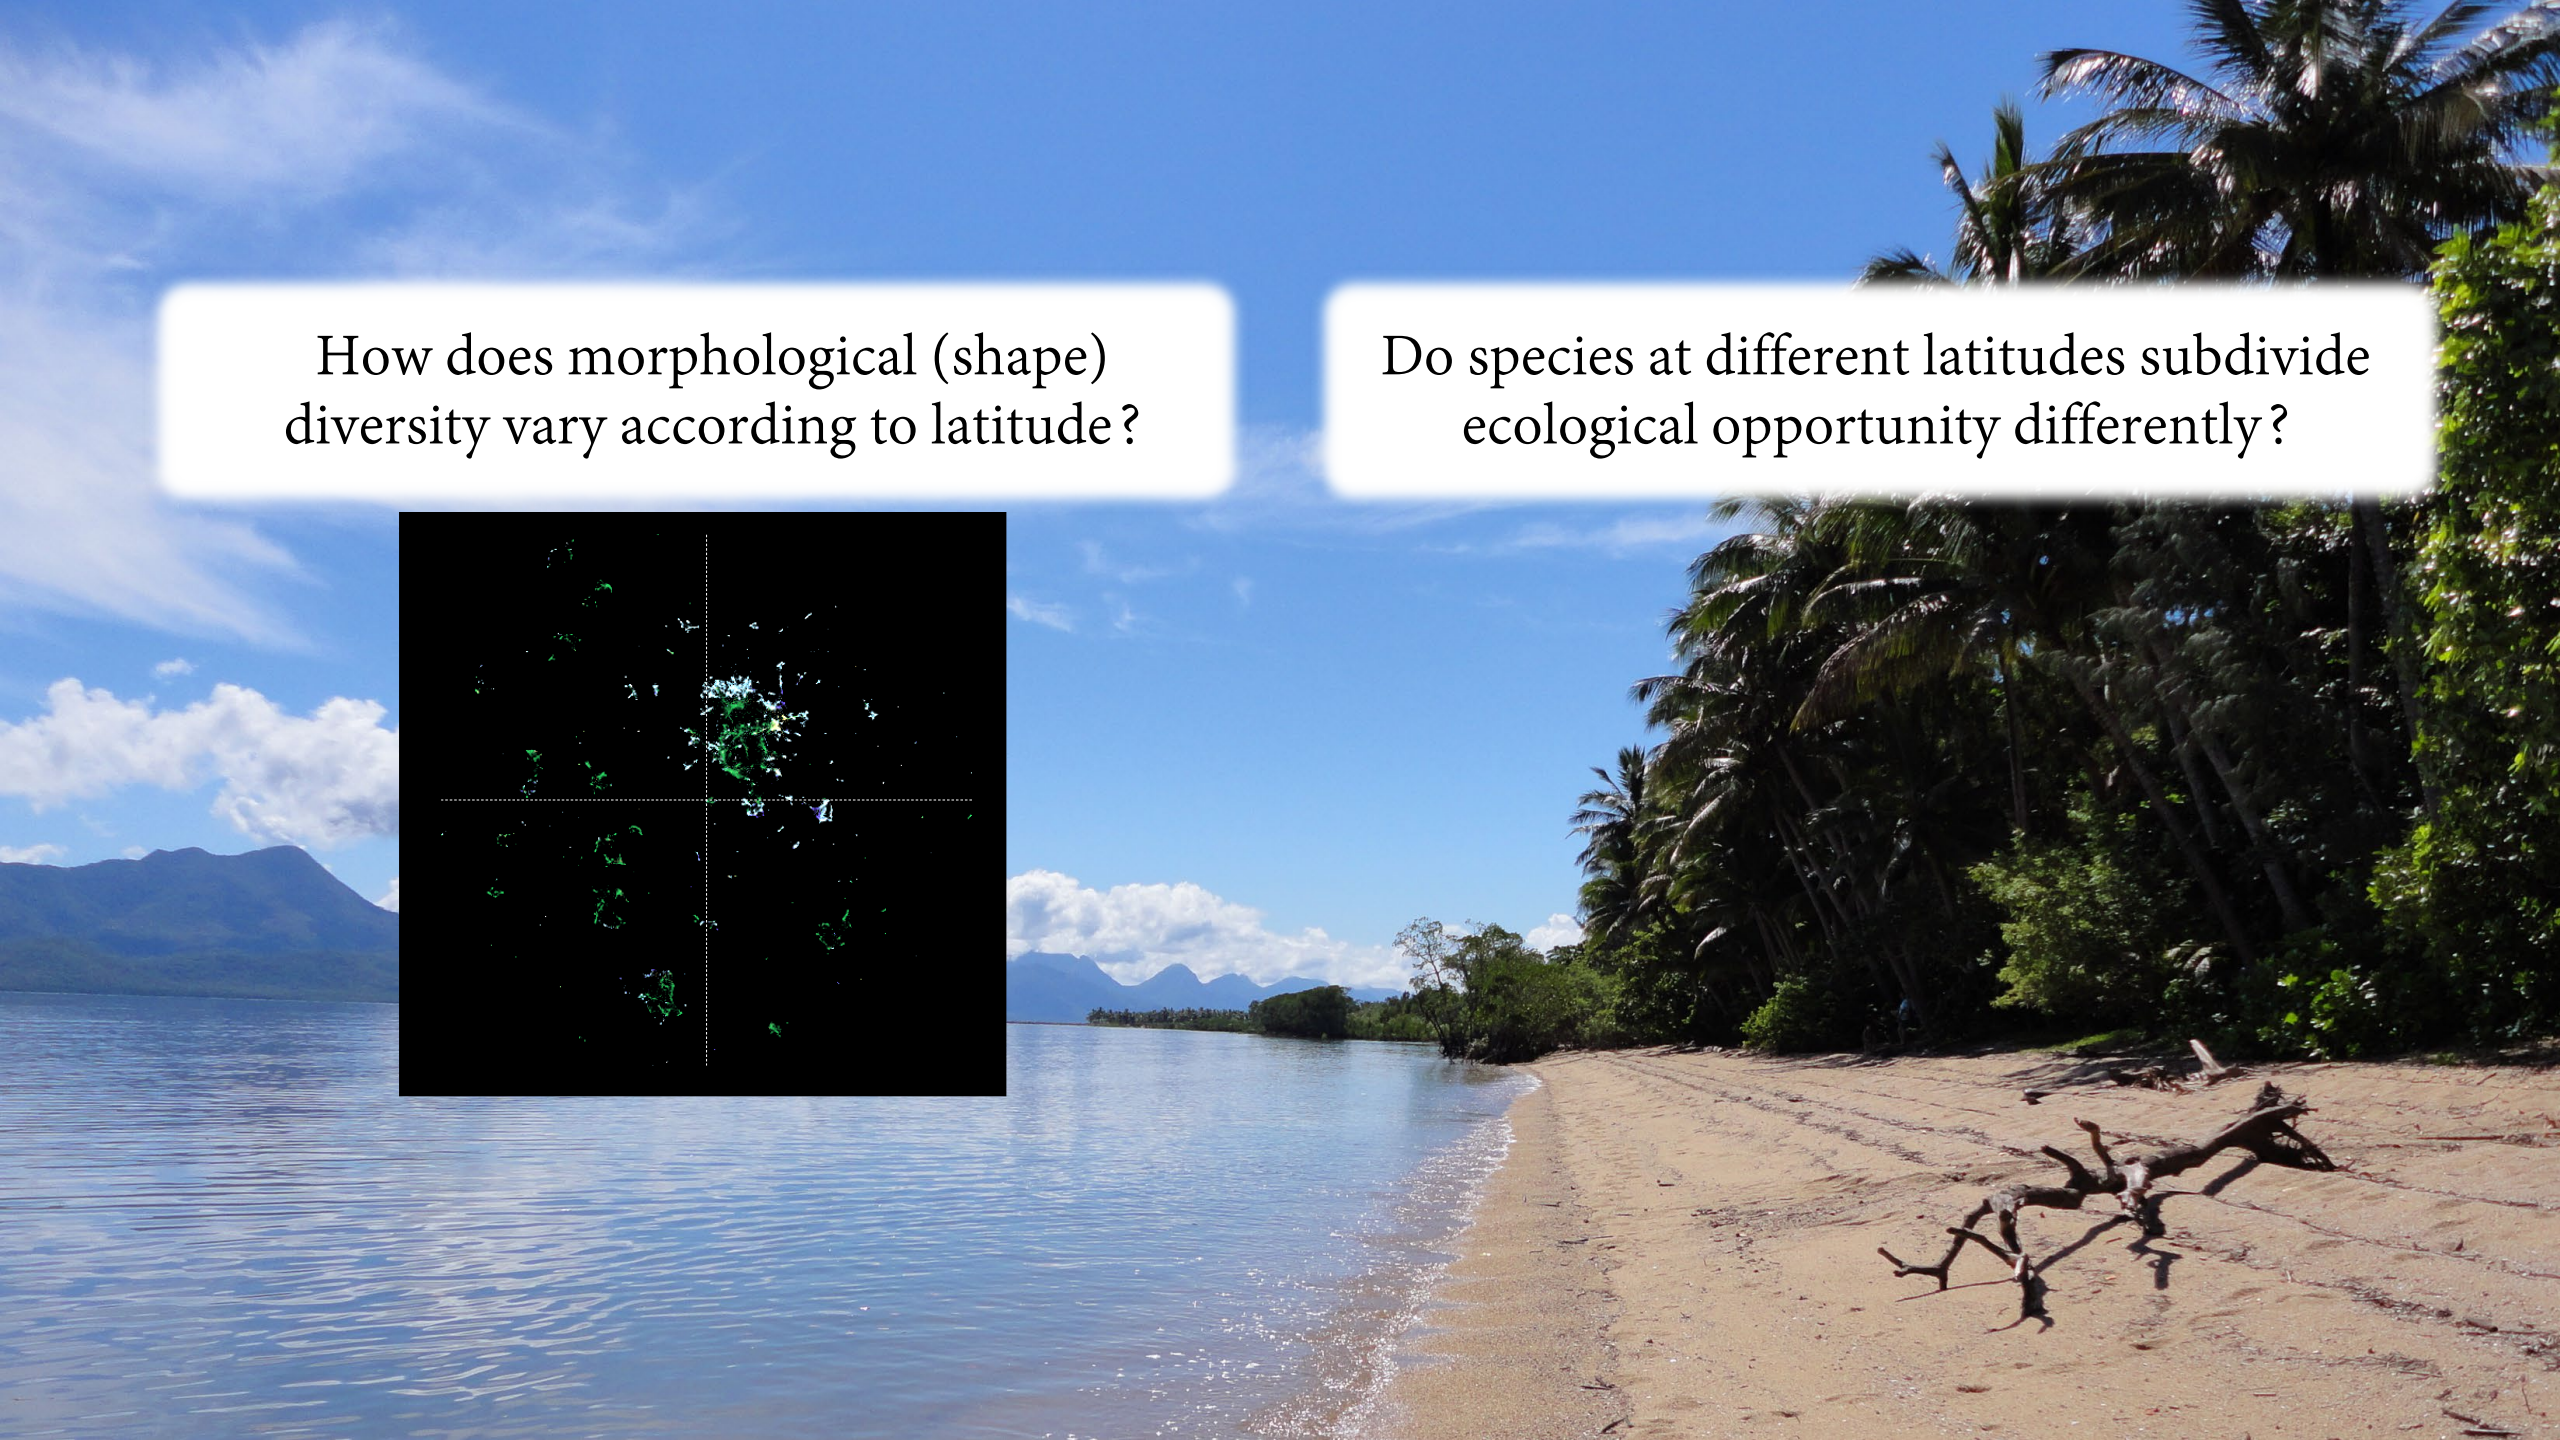

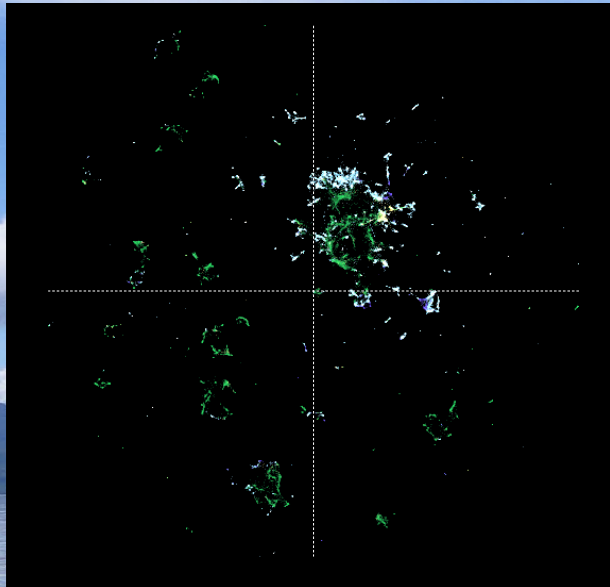

How does morphological (shape) diversity vary according to latitude?

Do species at different latitudes subdivide ecological opportunity differently?

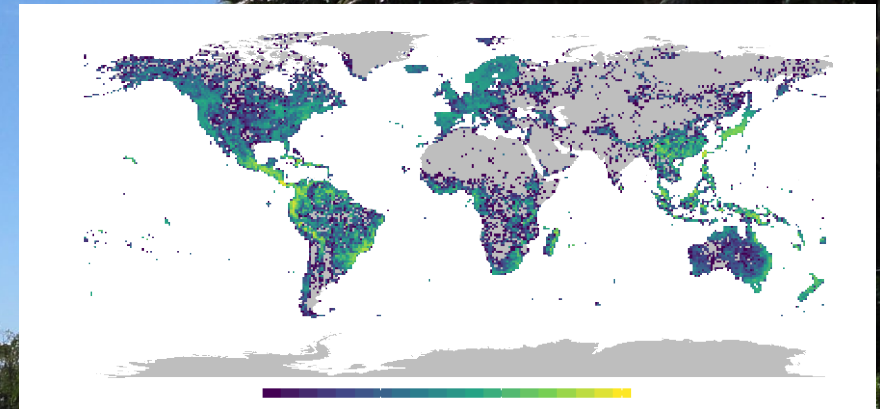

How does morphological (shape) diversity vary according to latitude?

Do species at different latitudes subdivide ecological opportunity differently?

How does morphological (shape) diversity vary according to latitude?

Do species at different latitudes subdivide ecological opportunity differently?

Extraneous objects could impact estimates of shape

So we are building masks to focus only on the plant in the image

So we are building masks to focus only on the plant in the image

What are the convolutional filters looking at?

4 example “feature maps”

early layer filters

late layer filters

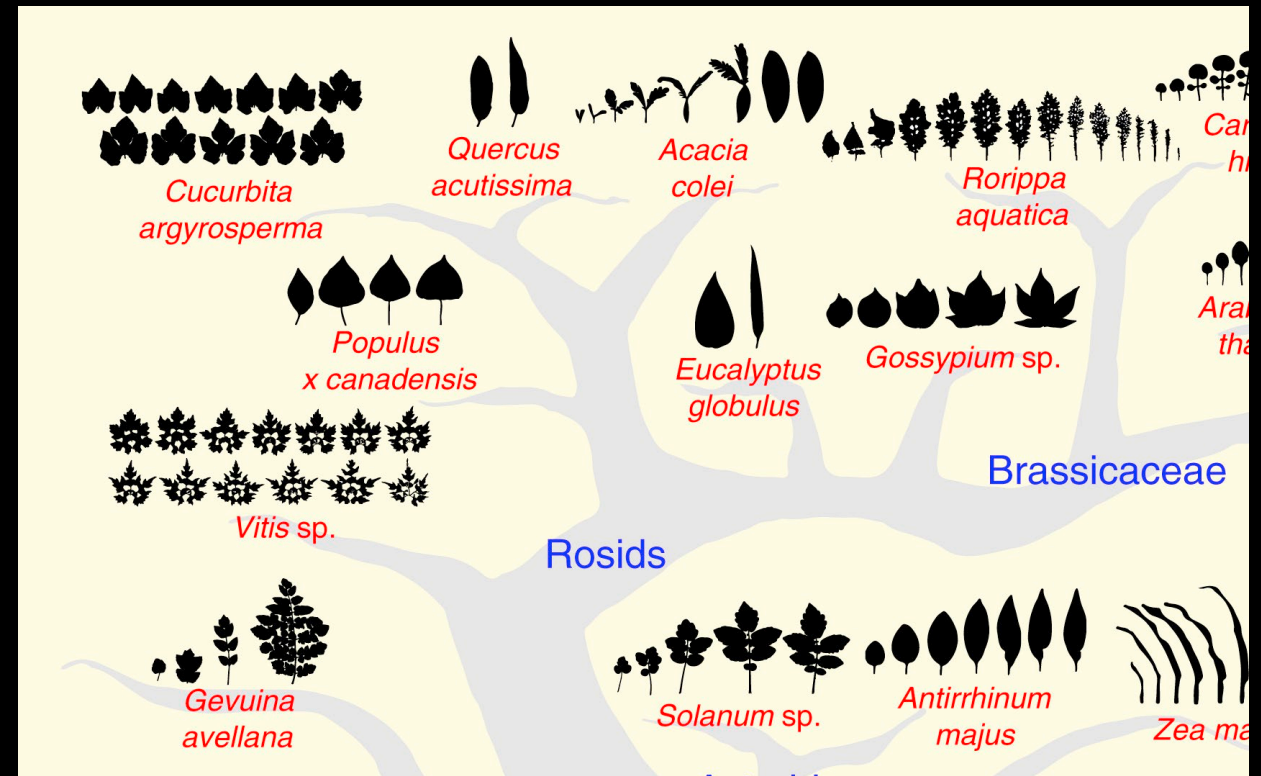

Plant leaf shapes are diverse and complex, with variations by latitude

Computer vision methods can help us quantify and summarize leaf shape
