Combining Non-invasive DNA extraction with Next-Generation Sequencing to study California Gall Wasps

Julian Rasco, Jeremy C. Andersen, Rosemary Gillespie, Nicholas J. Mills

University of California, Berkeley

Background
California oak gall wasps have intrigued researchers for decades due to their striking ability to induce vibrant growth of physically diverse structures from their host’s tissue. The galls’ primary function is to nourish the wasp’s larvae, protecting them while they are most vulnerable to predation. Most of the work done with gall wasps has focused on gall morphology, so very little is known about the wasps themselves. For example the underlying mechanism for gall formation is unknown, largely due to a lack of understanding of the phylogenetic relationships of oak gall wasps. This uncertainty in their taxonomy makes the California oak gall wasps an excellent candidate for research.2

Methods
1) Genetic material was isolated from 111 identified and 42 unidentified oak gall wasp specimens
2) Three genetic loci were targeted for PCR amplification (28S, COI, and LWRh)
3) Amplified fragments were barcoded with unique primer tails
4) Barcoded fragments were sequenced using the Illumina MiSeq Next-Generation Platform sequencing
5) Specimens were re-pinned and returned to the Essig Museum
6) Sequences were aligned to estimate a molecular phylogeny
7) Results were compared to published records for verification and to provide species-level IDs when possible

Results
1. Fragments of 28S, COI, and LWRh were amplified from 78, 27, and 124 specimens, respectively
2. Of those loci, only 28S sequenced successfully (32 specimens)
3. Ten specimens identified as gall formers, are actually inquilines
4. Only four species were reconstructed as monophyletic

Phylogenetic Reconstruction Based on 28S

Future Research
1. Use the morphological specimens to verify some of the misidentifications noted in our analysis
2. Use the 28S results to identify specimens to genus, and then to design genus-specific primers for COI and LWRh
3. Analyze factors that might have influenced the success of amplification and sequencing (e.g. age, collection method, DNA concentration, etc.)

Acknowledgements
This project was made possible by the generous donations of CNR alumni to the SPUR program. I would also like to thank Peter Oboyski for his mentorship & for allowing use of the museum's specimens. Finally, my greatest thanks to Joyce Gross, Kathy Schick, Diane Erwin, and members of the Gillespie lab for their guidance & assistance with the project.
